1 Introduction

The genefu package is providing relevant functions for gene expression analysis, especially in breast cancer. This package includes a number of algorithms for molecular subtype classification. The package also includes implementations of prognostic prediction algorithms, along with lists of prognostic gene signatures on which these algorithms were based.

Please refer to the manuscript URL and Lab website: http://www.pmgenomics.ca/bhklab/software/genefu Please also refer to the References section below, for additional information on publications that have cited Version 1 of genefu.

2 Loading package for case studies

First we load the genefu into the workspace. The pacakge is publicly available and can be installed from Bioconductor version 2.8 or higher in R version 2.13.0 or higher.

To install the genefu package:

^{*}benjamin.haibe.kains@utoronto.ca

```
knitr::opts_chunk$set(eval=TRUE, cache=TRUE)
source("http://bioconductor.org/biocLite.R")
biocLite("genefu")
```

For computing the risk scores, estimates of the performance of the risk scores, combining the estimates and comparing the estimates we have to load the genefu and survcomp packages into the workspace. We also load all the packages we need to conduct the case studies.

```
library(genefu)
library(xtable)
library(rmeta)
library(Biobase)
library(caret)
library(e1071)
```

3 Load Datasets and Packages for Case Studies

The following case study compares risk prediction models. This includes computing risk scores, computing estimates of the performance of the risk scores, as well as combining the estimates and comparing them.

The five data sets that we use in the case study are publicly available as experimental data packages on Bioconductor.org. In particular we used:

```
breastCancerMAINZ: http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerMAINZ.html
breastCancerUPP: http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerUPP.html
breastCancerUNT: http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerUNT.html
breastCancerNKI: http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerNKI.html
breastCancerTRANSBIG:http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerTRANSBIG.html
```

Please Note: We don't use the breastCancerVDX experimental package in this case study since it has been used as training data set for GENIUS. Please refer to Haibe-Kains et al, 2010. The breastCancerVDX is found at the following link:

breastCancerVDX: http://www.bioconductor.org/packages/release/data/experiment/html/breastCancerVDX.html

These experimental data packages can be installed from Bioconductor version 2.8 or higher in R version 2.13.0 or higher. For the experimental data packages the commands for installing the data sets are:

```
source("http://www.bioconductor.org/biocLite.R")
biocLite("breastCancerMAINZ")
biocLite("breastCancerTRANSBIG")
biocLite("breastCancerUPP")
biocLite("breastCancerUNT")
biocLite("breastCancerNKI")
```

And to load the packages into R, please use the following commands:

```
library(breastCancerMAINZ)
library(breastCancerTRANSBIG)
library(breastCancerUPP)
library(breastCancerUNT)
library(breastCancerNKI)
```

Table 1: Detailed overview for the data sets used in the case study

Dataset	Patients [#]	ER+ [#]	HER2+ [#]	Age [years]	Grade $[1/2/3]$	Platform
MAINZ	200	155	23	25-90	29/136/35	HGU133A
TRANSBIG	198	123	35	24-60	30/83/83	HGU133A
UPP	251	175	46	28-93	67/128/54	HGU133AB
UNT	137	94	21	24-73	32/51/29	HGU133AB
NKI	337	212	53	26-62	79/109/149	Agilent
Overall	1123	759	178	25-73	237/507/350	Affy/Agilent

Table 1 shows an overview of the data sets and the patients. From those 1123 breast cancer patients we selected only the patients that are node negative and didn't receive any treatment (except local radiotherapy), which results in 713 patients.

Since there are duplicated patients in the five data sets, we have to identify the duplicated patients and we subsequently store them in a vector.

```
data(breastCancerData)
cinfo <- colnames(pData(mainz7g))</pre>
data.all <- c("transbig7g"=transbig7g, "unt7g"=unt7g, "upp7g"=upp7g, "mainz7g"=mainz7g, "nki7g"=nki7g)
idtoremove.all <- NULL</pre>
duplres <- NULL
## No overlaps in the MainZ and NKI datasets.
## Focus on UNT vs UPP vs TRANSBIG
demo.all <- rbind(pData(transbig7g), pData(unt7g), pData(upp7g))</pre>
dn2 <- c("TRANSBIG", "UNT", "UPP")</pre>
## Karolinska
## Search for the VDXKIU, KIU, UPPU series
ds2 <- c("VDXKIU", "KIU", "UPPU")</pre>
demot <- demo.all[complete.cases(demo.all[ , c("series")]) & is.element(demo.all[ , "series"], ds2), ]</pre>
# Find the duplicated patients in that series
duplid <- sort(unique(demot[duplicated(demot[ , "id"]), "id"]))</pre>
duplrest <- NULL</pre>
for(i in 1:length(duplid)) {
 tt <- NULL
 for(k in 1:length(dn2)) {
    myx <- sort(row.names(demot)[complete.cases(demot[ , c("id", "dataset")]) &</pre>
                                      demot[ , "id"] == duplid[i] & demot[ , "dataset"] == dn2[k]])
    if(length(myx) > 0) { tt <- c(tt, myx) }</pre>
  duplrest <- c(duplrest, list(tt))</pre>
names(duplrest) <- duplid</pre>
duplres <- c(duplres, duplrest)</pre>
## Oxford
## Search for the VVDXOXFU, OXFU series
ds2 <- c("VDXOXFU", "OXFU")</pre>
demot <- demo.all[complete.cases(demo.all[ , c("series")]) & is.element(demo.all[ , "series"], ds2), ]</pre>
```

4 Case Study: Compare Molecular Subtype Classifications

For this case study, we first created a merged expression set that combines all the samples across the 5 datasets. To do this we first select for the most representative probes across the esets and get the corresponding gene ids. We then perform quantile normalization on the gene expression datasets to merge them.

```
library(WGCNA)
## Loading required package:
                              dynamicTreeCut
## Loading required package:
                              fastcluster
##
## Attaching package: 'fastcluster'
##
## The following object is masked from 'package:stats':
##
##
      hclust
##
## Loading required package: DBI
## *
## *
      Package WGCNA 1.47 loaded.
## *
## *
        Important note: It appears that your system supports multi-threading,
        but it is not enabled within WGCNA in R.
## *
        To allow multi-threading within WGCNA with all available cores, use
## *
## *
              allowWGCNAThreads()
## *
        within R. Use disable WGCNAThreads() to disable threading if necessary.
## *
        Alternatively, set the following environment variable on your system:
## *
## *
              ALLOW_WGCNA_THREADS=<number_of_processors>
## *
```

```
## *
        for example
## *
## *
              ALLOW_WGCNA_THREADS=4
## *
## *
        To set the environment variable in linux bash shell, type
## *
## *
               export ALLOW_WGCNA_THREADS=4
## *
## *
         before running R. Other operating systems or shells will
         have a similar command to achieve the same aim.
## *
## Attaching package: 'WGCNA'
## The following object is masked from 'package:stats':

# BIND ALL TOGETHER
res <- rbind(res, rest)
}
names(ddemo.all) <- dn</pre>
```

For further analysis and handling of the data we store all information in one object. We also remove the duplicated patients from the analysis and take only those patients into account, that have complete information for nodal, survival and treatment status.

```
ddemot <- NULL
for(i in 1:length(ddemo.all)) {
  ddemot <- rbind(ddemot, ddemo.all[[i]][ , ddemo.coln, drop=FALSE])</pre>
res[complete.cases(ddemot[ ,"dataset"]) & ddemot[ ,"dataset"] == "VDX", "GENIUS"] <- NA
## select only untreated node-negative patients with all risk predictions
## ie(incomplete cases (where a risk prediction may be missing for a sample) are subsequently removed))
# Note that increasing the number of risk prediction analyses
# may increase the number of incomplete cases
# In the previous vignette for genefu version1, we were only testing 4 risk predictors,
# so we had a total of 722 complete cases remaining
# Here, we are now testing 12 risk predictors, so we only have 713 complete cases remaining.
# The difference of 9 cases between the two versions are all from the NKI dataset.
myx <- complete.cases(res, ddemot[ , c("node", "treatment")]) &</pre>
  ddemot[ , "treatment"] == 0 & ddemot[ , "node"] == 0 & !is.element(rownames(ddemot), duPL)
res <- res[myx, , drop=FALSE]</pre>
ddemot <- ddemot[myx, , drop=FALSE]</pre>
```

To compare the risk score performances, we compute the concordance index¹:

Definition of the concordance index for a risk prediction: the probability that, for a pair of randomly chosen comparable samples, the sample with the higher risk prediction will experience an event before the other sample or belongs to a higher binary class.

¹The same analysis could be performed with D index and hazard ratio by using the functions D.index and hazard.ratio from the *survcomp* package respectively

```
cc.res <- complete.cases(res)</pre>
datasetList <- c("MAINZ","TRANSBIG","UPP","UNT","NKI")</pre>
riskPList <- c("AURKA", "ESR1", "ERBB2", "NPI", "GGI", "GENIUS",
                "EndoPredict", "OncotypeDx", "TAMR13", "GENE70", "PIK3CA", "rorS")
setT <- setE <- NULL
resMatrix <- as.list(NULL)</pre>
for(i in datasetList)
{
  dataset.only <- ddemot[,"dataset"] == i</pre>
  patientsAll <- cc.res & dataset.only</pre>
  ## set type of available survival data
  if(i == "UPP") {
    setT <- "t.rfs"
    setE <- "e.rfs"
  } else {
    setT <- "t.dmfs"</pre>
    setE <- "e.dmfs"
  # Calculate cindex computation for each predictor
  for (Dat in riskPList)
    cindex <- t(apply(X=t(res[patientsAll,Dat]), MARGIN=1, function(x, y, z) {</pre>
    tt <- concordance.index(x=x, surv.time=y, surv.event=z, method="noether", na.rm=TRUE);</pre>
    return(c("cindex"=tt$c.index, "cindex.se"=tt$se, "lower"=tt$lower, "upper"=tt$upper)); },
    y=ddemot[patientsAll,setT], z=ddemot[patientsAll, setE]))
    resMatrix[[Dat]] <- rbind(resMatrix[[Dat]], cindex)</pre>
  }
}
```

Using a random-effects model we combine the dataset-specific performance estimated into overall estimates for each risk prediction model:

```
for(i in names(resMatrix)){
    #Get a meta-estimate
    ceData <- combine.est(x=resMatrix[[i]][,"cindex"], x.se=resMatrix[[i]][,"cindex.se"], hetero=TRUE)
    cLower <- ceData$estimate + qnorm(0.025, lower.tail=TRUE) * ceData$se
    cUpper <- ceData$estimate + qnorm(0.025, lower.tail=FALSE) * ceData$se

    cindex0 <- cbind("cindex"=ceData$estimate, "cindex.se"=ceData$se, "lower"=cLower, "upper"=cUpper)
    resMatrix[[i]] <- rbind(resMatrix[[i]], cindex0)
    rownames(resMatrix[[i]]) <- c(datasetList, "Overall")
}</pre>
```

In order to compare the different risk prediction models we compute one-sided p-values of the metaestimates:

```
pv <- sapply(resMatrix, function(x) { return(x["Overall", c("cindex","cindex.se")]) })
pv <- apply(pv, 2, function(x) { return(pnorm((x[1] - 0.5) / x[2], lower.tail=x[1] < 0.5)) })
printPV <- matrix(pv,ncol=length(names(resMatrix)))
rownames(printPV) <- "P-value"</pre>
```

```
colnames(printPV) <- names(pv)
printPV<-t(printPV)</pre>
```

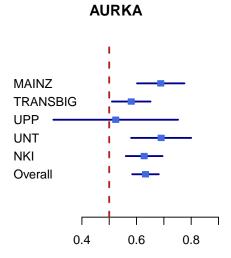

And print the table of P-values:

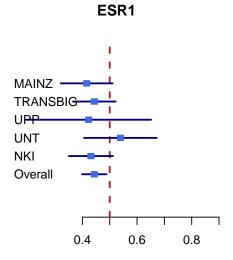

```
xtable(printPV, digits=c(0, -1))
```

	P-value
AURKA	4.5E-08
ESR1	6.5E-03
ERBB2	4.6E-01
